A general-purpose language for clear software

Basic Next (BN) is a general-purpose, object-oriented programming language designed to reduce cognitive load and turn ideas into clear, cross-platform software. It combines BASIC-inspired readability with explicit types, cohesive objects, and capability-based access to the host environment.

BN is not a nostalgia project and is not a framework. Its goal is a small language core that keeps everyday code readable while leaving room for serious software: command-line tools, data work, applications, integrations, and future device or web targets.

The design in one example

```
IMPORT HOST.main AS main

FUNCTION Start() AS VOID
  LET counter AS INTEGER = 0

  WHILE counter < 10
    PRINT "Basic Next", counter
    counter += 1
  END WHILE
END FUNCTION
```

The program begins in an explicit method, uses readable control flow, and does not require a ceremony-heavy application class or a framework to do simple work.

What BN values

- **Readable source:** code is communication before it is instruction.
- **Explicit contracts:** types, visibility, imports, and host capabilities are visible in the source.
- **Object-oriented structure:** behavior lives in cohesive classes; public and

private boundaries are deliberate.

- **Small core:** language keywords solve fundamental problems; libraries and host capabilities carry the rest.

- **Cross-platform reach:** software targets HOST capabilities rather than a particular vendor API.

Current status

BN is pre-implementation. The Basic Next 0.1 specification is being written before the interpreter, runtime, and package workflow are built. This is a deliberate choice: the project will validate semantics through examples and proposals before treating them as implementation commitments.

The promise

Basic Next aims to make the common case calm and understandable, while keeping explicit mechanisms available when software needs structure, types, memory, or host integration.
